3.6 Geology, Soils, and Mineral Resources

This section describes the environmental and regulatory settings and draft significance criteria with respect to geology, soils, and mineral resources.

3.6.1 Environmental Setting

This subsection describes the environmental setting for geology, soils, and mineral resources. In this section, the “study area” refers to the land beneath the proposed project components (i.e., temporary workspace, permanent right-of-way [ROW], and aboveground facilities).

3.6.1.1 Geology

Topography
Topography within the study area ranges from nearly flat to steeply sloping. Elevations in the study area range from approximately 100 meters (328 feet) to approximately 350 meters (1,255 feet) above mean sea level (USGS n.d.). Significant portions of the study area are located on slopes that exceed 25 percent (County of San Diego OES and San Diego County UDC 2010).

Geomorphic Setting
The study area is located in the western portion of the geomorphic province of California known as the Peninsular Ranges province. The Peninsular Ranges province is bounded on the east and north by the Colorado Desert and Transverse Ranges provinces, on the south by primarily intrusive rocks in Mexico, and on the west by the edge of the continental shelf (Ledesma-Vazquez et al. 2009). The Peninsular Ranges are separated by northwest-trending valleys, subparallel to faults branching from the San Andreas fault zone. Geology in the Peninsular Ranges province is similar to that of the Sierra Nevada of California, with granitic rocks intruding into older metamorphic rocks (CGS 2002).

Geologic Units
Surficial geology underlying the study area consists of alluvium, sedimentary rocks, intermediate volcanic rocks, and plutonic rocks. Alluvium underlies the study area primarily near watercourses and water bodies. Sedimentary rocks underlying the study area include argillite, mudstone, sandstone, and conglomerate. Plutonic rocks underlying the study area include tonalite, diorite, quartz diorite, and gabbro.

Surficial geology underlying Line 3602 and associated support facilities consists of alluvium, argillite, mudstone, sandstone, conglomerate, tonalite, diorite, quartz diorite, gabbro, and intermediate volcanic rocks. The regulator stations that would be removed along Line 1600 are underlain primarily by conglomerate and sandstone, with some specific stations or portions of them underlain by alluvium, intermediate volcanic rock, tonalite, and quartz diorite. The Mira Mesa Pipeline Extension and Line 49-31B Replacement are underlain by alluvium, conglomerate, and sandstone. The permanent patrol road is underlain by conglomerate and sandstone. Temporary access roads are underlain by tonalite, quartz diorite, gabbro, diorite, argillite, and greywacke. The staging areas/laydown yards are mostly underlain by tonalite and quartz diorite, with some yards or portions of them underlain by conglomerate, sandstone, gabbro, diorite, argillite, and greywacke. Geologic units associated with each proposed project component are listed in Table 3.6-1. Geology below and near each proposed project component is shown on Figure 3.6-1.

Soils

The soils in the study area have been mapped by the U.S. Department of Agriculture Natural Resources Conservation Service (NRCS). The NRCS maintains an online database of soil survey data for most United States counties through the Soil Survey Geographic database (NRCS 2017). The NRCS soil survey data describe the types of soils that exist in an area, their locations on the landscape, and their suitability for various uses. Soils of a similar type are grouped into soil map units. The major soil map units within the study area are presented in Table 3.6-2. The extent of the soil series underlying the study area is shown on Figure 3.6-2.

</table>

Source: NRCS 2017

Notes:
(a) Linear extensibility of less than 3 percent = low shrink-swell potential; 3 to 6 percent = moderate potential; 6 to 9 percent = high potential; greater than 9 percent = very high potential. The reported values were calculated by the NRCS as shrink swell potential posed to small commercial buildings.
(b) Erosion hazard interpreted by NRCS for unsurfaced roads and trails.
(c) Soils are assigned to wind erodibility groups based on their susceptibility to wind erosion. Soils assigned to Group 1 are the most susceptible; soils assigned to Group 8 are the least susceptible.

Line 3602 and Associated Support Facilities

Soils underlying Line 3602 and associated support facilities, as defined above, consist primarily of sandy loams that are in some areas rocky, gravelly, or cobbly. Clay, silt, silt loam, gravelly or cobbly loam, and loam also underlie portions of Line 3602 and associated support facilities. Most of the soil series underlying Line 3602 and associated support facilities have low to moderate shrink-swell potential. Following are the series and map symbols for soils underlying Line 3602 with high or very high shrink-swell potential: Bonsall Sandy Loam (BIC), Bosanko Clay (BsD), Diablo-Olivenhain Complex (DoE), Huerhuero Loam (HrC), Las Posas Sandy Loams (LpC, LpD2, and LrG), Placentia Sandy Loam (PfC), Redding Cobbly Loams (ReE and RfF), and San Miguel Rocky Silt Loam (SmE).

A number of the soil series underlying Line 3602 and associated support facilities are ranked as posing a severe erosion hazard. The series names and map symbols for soils underlying Line 3602 and associated support facilities with a severe erosion hazard ranking are: Cienebra Sandy Loams (CID2, CIE2, CmE2, and CmrG), Cienebra-Fallbrook Rocky Sandy Loams (CnE2 and CnG2), Diablo Clay (DaE), Diablo-Olivenhain Complex (DoE), Escondido Very Fine Sandy Loams (EsD2 and EsE2), Fallbrook Sandy Loams (FaD2 and FaE2), Fallbrook-Vista Sandy Loams (FvD and FvE), Friant Fine Sandy Loam (FwF), Las Posas Sandy Loams (LpC, LpD2, and LrG), Placentia Sandy Loam (PeD2), Ramona Sandy Loam (RaD2), Redding Cobbly Loams (ReE and RfF), San Miguel Rocky Silt Loam (SmE), Vista Sandy Loams (VsD, VsD2, VsE, VsE2, VsG, VvD, and VvG), and Wyman Loam (WmD).
Line 1600 Regulator Station Removals and Replacements with Check Valves
Soils underlying the regulator stations along Line 1600 that would be removed (Regulator Stations 141, 982, 939, 1051, 1101, 1248, 1316, 1335, 1494, 1500, and 1516) consist of Diablo Clay (DaD and DaE), Fallbrook-Vista Sandy Loam (FvE), Redding Gravelly/Cobbly Loams (RdC and ReE), and San Miguel Rocky Silt Loam (SmE). Regulator Stations 1316, 1500, and 1516 would be replaced with check valves. Regulator Station 939 would be replaced with a new regulator station. Except for one of the Diablo Clay Units and the Redding Gravelly Loam, which pose a moderate erosion hazard, these soil series pose a severe erosion hazard. Except for the moderate shrink-swell potential of Redding Gravelly Loam, all of these soil series have high or very high shrink-swell potential.

Mira Mesa Pipeline Extension
The Mira Mesa Pipeline Extension is underlain by the Redding Gravelly Loam, which has a moderate shrink-swell potential and poses a moderate erosion hazard.

Line 49-31B Replacement
The Line 49-31B Replacement is underlain by the Redding Gravelly Loam, Redding Cobbly Loam, and Riverwash. The Redding Cobbly Loam has a high shrink-swell potential and poses a severe erosion hazard. Riverwash is considered by the NRCS as a miscellaneous area and not a soil series; therefore, they do not provide shrink-swell potential or erosion hazard rankings for it.

Access and Patrol Roads
Existing access roads located between Mileposts (MPs) 3.0 and 4.0 would be utilized to access a portion of the Line 3602 and associated support facilities construction area. The existing access roads are underlain by Las Posas Stony Fine Sandy Loam and Wyman Loam, which both pose severe erosion potential. Two new access roads would be constructed between MPs 12.0 and 13.0. These two roads are underlain by Cienega Coarse Sandy Loam and Fallbrook Sandy Loams. The Cienega soil poses a severe erosion hazard, while the Fallbrook soil poses a moderate erosion hazard. One new permanent patrol road would be constructed between MPs 43.0 and 44.0. The patrol road is underlain by Redding Gravelly Loam, Redding Cobbly Loam, and Riverwash. Redding Gravelly Loam poses a moderate erosion hazard, Redding Cobbly Loam poses a severe erosion hazard, and Riverwash is not ranked for erosion hazard.

Staging Areas/Laydown Yards
Soils underlying the staging areas/laydown yards consist mostly of sandy loam with areas of loam, silt loam, and gravelly or cobbly loam. Soils underlying Staging Areas/Laydown Yards #2, #5A, #5C, and #6A pose severe erosion potential. Soils underlying the remaining staging areas/laydown yards pose a slight to moderate erosion potential.

3.6.1.2 Geologic Hazards

Faulting and Seismicity
The Alquist-Priolo Earthquake Fault Zoning Act (Public Resources Code Division 7, Chapter 2.5) requires the delineation of earthquake faults for the purpose of protecting public safety. Faults included in the Alquist-Priolo Earthquake Fault Zoning Program are classified by activity as follows (CGS 2007):

- Faults classified as “active” are those that have been determined to be “sufficiently active and well defined,” with evidence of movement within Holocene time (within the past 11,000 years).
- Faults classified as “potentially active” have shown geologic evidence of movement during Quaternary time (within the last 1.6 million years).
- Faults considered “inactive” have not moved in the last 1.6 million years.
Active and potentially active faults are present within 25 miles of the study area, as shown on Figure 3.6-3. Alquist-Priolo Earthquake Fault Zones (A-P fault zones) are designated areas within 500 feet of a known active fault trace. The proposed project components would not cross any active faults or potentially active faults; therefore, the proposed project components would cross no A-P fault zones. A number of active and potentially active faults are located near the study area (Jennings and Bryant 2010). These active and potentially active faults have the potential to cause strong ground shaking in the study area as a result of an earthquake. Information regarding active and potentially active faults within 25 miles of the study area is presented in Table 3.6-3. Active and potentially active faults within 25 miles of the study area are shown on Figure 3.6-3.

</tbody>
</table>
Faults generally produce damage in two ways: ground shaking and surface rupture. Seismically induced ground shaking covers a wide area and is greatly influenced by the distance to the seismic source, soil conditions, and groundwater depth. Surface rupture is limited to the areas closest to the faults. Other potential hazards associated with seismically induced ground shaking include earthquake-triggered landslides, liquefaction, and tsunamis.

Only five historical earthquakes over moment magnitude 4 have occurred within approximately 25 miles of the study area (USGS 2017b). Magnitudes of historical earthquakes range up to moment magnitude 6.7. The locations of historical earthquakes and active or potentially active faults within 25 miles of the study area are shown on Figure 3.6-3.

Seismic hazards in a region are estimated by statistical analysis of earthquake occurrence to determine the level of potential ground motion. A common parameter used for estimating ground motion at a particular location is the peak ground acceleration (PGA). PGA is a measure of earthquake intensity; it indicates how hard the earth shakes at a given geographic location during the course of an earthquake. PGA values are typically expressed as a percentage of acceleration due to gravity: the higher the PGA value, the more intense the ground shaking.\(^1\) PGA values were calculated by the California Geological Survey (CGS) based on historical earthquake occurrence, known damage from historic earthquakes, slip rates of major faults, and geologic materials. The PGA values described below were obtained through the CGS online ground motion interpolator (CGS 2008). The PGA values calculated by the CGS in the vicinity of the various proposed project components range from 0.417 to 0.668 times the force of gravity (g) with a 2 percent chance of being exceeded in 50 years (CGS 2008). The PGA values calculated by the CGS with a 10 percent chance of being exceeded in 50 years range from 0.241 to 0.378 g. The highest PGA values occur at the north end of the study area, and the lowest near the south end. PGA values vary throughout the study area and would be assessed as part of a site-specific geotechnical analysis. The assessed PGA values would be used to ensure that a proposed project is designed in compliance with applicable building codes.

**Erosion**

Water and wind are the processes responsible for most soil erosion within the study area. The NRCS assigns soils to Wind Erodibility Groups (WEGs). The susceptibility of the soils in the study area to wind erosion ranges from WEG 1 (highly susceptible) to WEG 7 (slightly susceptible), with most soils ranking moderately susceptible at WEG 3 to 4. The NRCS ranks the erosion hazard of soils for roads and trails at the site ranging from slight to severe. Soils that rank with a high or severe erosion hazard are present at

---

\(^1\) The acceleration due to gravity is relatively constant at the earth’s surface: 980 centimeters per second per second (cm/sec/sec). An acceleration of 16 feet per second is 16*12*2.54 = 487 cm/sec/sec. Therefore, an acceleration of 16 feet per second = 487/980 = 0.50 g.
various locations within the study area. Information regarding soil characteristics in the study area is presented in Table 3.6-2. The extent of soils described here is shown on Figure 3.6-2.

**Landslides**

Landslides may occur naturally or result from construction activities that remove stabilizing vegetation, create over-steepened slopes, or concentrate runoff onto existing landslides or areas susceptible to landslides. The San Diego County Multi-jurisdictional Hazard Mitigation Plan (Hazard Mitigation Plan) maps landslides, landslide susceptibility, and slide-prone formations in San Diego County (County of San Diego OES and San Diego County UDC 2010). Line 3602 would cross an area mapped as underlain by slide-prone formations and landslides from approximately 500 feet north of MP 46.0 through the terminus of Line 3602 at MP 47.3. Along Line 1600, Regulator Stations 141 and 1516 are underlain by slide-prone formations, and Regulator Station 1101 appears to be underlain by landslides. No other proposed project components would cross areas mapped as susceptible to landslides, known landslides, or slide-prone formations, according to the Hazard Mitigation Plan.

The U.S. Geological Survey (USGS) maps landslides on its Landslide Overview Map of the Conterminous United States and landslide susceptibility on its Landslide Susceptibility from the National Atlas of the United States (USGS 1982, 1997). The USGS maps the area around Line 1600, which includes Regulator Stations 1101, 1516, 141, 1500, and 1248, as having moderate landslide susceptibility and as a landslide occurrence area. The areas around all other proposed project components are mapped by the USGS as having a low susceptibility to landslides. Portions of the Line 3602 route from MP 0.0 to 18.5, and a small area around MP 40.0, are mapped as landslide occurrence areas. Proposed project components located in landslide occurrence areas are: portions of Line 3602; existing access roads between MPs 3.0 and 4.0; temporary access roads between MPs 12.0 and 13.0; and Staging Areas/Laydown Yards #1, #2, and #4. Landslide susceptibility and occurrence areas are shown on Figure 3.6-4.

**Liquefaction**

Liquefaction can occur during an earthquake in areas where unconsolidated sediments and a shallow water table are present. Liquefaction occurs when seismic ground motion causes saturated sediments to flow like a fluid, resulting in sand boils or lateral spreading, both of which may cause a decrease in structural bearing capacity that can result in structural settlement or collapse. The Hazard Mitigation Plan maps liquefaction risk and liquefiable soils (labeled on the plan map as liquefaction layers) in San Diego County (County of San Diego OES and San Diego County UDC 2010). While the proposed project components would cross areas of liquefiable soil primarily at and near watercourse crossings, all but a small portion of the study area would be located in areas mapped as posing low liquefaction risk. Only the portion of the study area from approximately MP 4.5 to the northern terminus of Line 3602 would be located in an area mapped as having high liquefaction risk.

**Subsidence/Collapsible Soil**

Land subsidence can occur where large volumes of fluids are pumped from underground, such as near water wells or oil fields. Land subsidence occurs because the fluids present in subsurface pore spaces partially provide bearing capacity to support rock or sediments. When large volumes of fluids are pumped from the subsurface, land subsidence can result when rock or sediment partially collapses under its own weight into pore spaces that were previously full of fluids. Some soil may also collapse if it is irrigated after remaining dry for long periods of time. The County of San Diego General Plan does not discuss land subsidence or the presence of collapsible soil as hazards in the county (County of San Diego 2015). The Hazard Mitigation Plan does not consider land subsidence or collapsible soils as significant hazards in the county. Land subsidence was not considered in the risk assessment portion of the Hazard Mitigation Plan because there is no historical record of land subsidence in the county and because it presents only a minor threat to limited parts of the county. The hazards of collapsible soil are not discussed in the Hazard Mitigation Plan.
3.6 GEOLOGY, SOILS, AND MINERAL RESOURCES

3.6-13

Expansive Soil
Some soils contain certain clay minerals that may cause them to swell when moist and shrink as the soil dries. These soils are known as expansive soils. Expansive soils have the potential to disturb building foundations, walls, roads, and pipeline components in areas underlain by expansive soils. Proposed project components that are at least partially underlain by soils with high to very high shrink-swell potential are: Line 3602 and associated support facilities; Line 1600 Regulator Stations 141, 982, 1101, 1248, 1500, and 1516; Line 49-31B Replacement; existing access roads between MPs 3.0 and 4.0; the permanent patrol road; and Staging Areas/Laydown Yards #2 and #5A. Table 3.6-2 lists the soil types and characteristics for the soils underlying the study area, including shrink-swell potential. The extent of the various soil series below the study area is shown on Figure 3.6-2.

3.6.1.3 Mineral Resources
According to the USGS, a mineral resource is defined as a concentration of naturally occurring solid, liquid, or gaseous material in or on the earth’s crust in such form and amount that economic extraction of a commodity from the concentration is currently or potentially feasible (USGS 1980). Mineral resources include oil, natural gas, metallic deposits, and non-metallic deposits.

The study area is not located in a region of active oil exploration and production. No active oil or gas wells are located within the study area; however, there are a few idle, buried, plugged and abandoned, and unknown status wells within a few miles of some proposed project components. In addition, the study area is not located within the boundaries of an oil and gas field (DOC 2001). Figure 3.6-5 shows the locations of oil and gas wells near the study area (DOC 2017).

The Mineral Resource Data System of the USGS maps current and past producers of minerals, prospects, and occurrences of minerals. A small number of past producers and current producers of mineral resources are located within 0.25 mile of Line 3602, as discussed here (USGS 2003). Two past producers of sand and gravel for construction are located west of Line 3602 near MP 13.5; however, both appear to be within the Interstate (I-) 15 ROW such that future mining would be precluded by the presence of I-15. A former producer of perlite is located near I-15 and Centre City Parkway, such that the presence of the street and surrounding urban development would preclude mining. A gold prospect also is located near Regulator Station 1316; however, removal of the regulator station would not prevent mining at this location. East of Line 3602, near MP 31.3, is a stone producer; however, current aerial photography shows this area to be developed with residential housing such that it clearly is not a current producer. A past producer of crushed stone is located east of Line 3602 near MP 37.8; however, at this site, Line 3602 is located within the public ROW in Pomerado Road and mining would already be precluded by the presence of Pomerado Road. No active or inactive mines, no mineral occurrences, and no mineral prospects are known to exist within the study area (USGS 2003).

The California Department of Conservation, Division of Mines and Geology mapped mineral resource zones in the vicinity of the study area in its Special Report 153 (DOC 1982). The designated mineral resource zones (MRZ) in the study area are for aggregate resources and defined as follows:

**MRZ-1**: Areas where adequate information indicates that no significant mineral deposits are present, or where it is judged that there is little likelihood for their presence. This zone shall be applied where well-developed lines of reasoning, based upon economic-geologic principles and adequate data, demonstrate that the likelihood for occurrence of significant mineral deposits is nil or slight.

**MRZ-2**: Areas where adequate information indicates that significant mineral deposits are present, or where it is judged that there is a high likelihood for their presence. This zone shall be applied to known mineral deposits or where well-developed lines of reasoning,
based on economic-geologic principles and adequate data, demonstrate that the likelihood for occurrence of significant mineral deposits is high.

**MRZ-3:** Areas containing mineral deposits; the significance of which cannot be evaluated from available data.

**MRZ-4:** Areas where available information is inadequate for assignment to any other mineral resource zone (DOC 1982).

Areas designated as MRZ-2 (where mineral resources are present) are located within the floodplain of the San Luis Rey River, on the bed of Lake Hodges, and in the southern portions of the study area. MRZs in the study area are shown on Figure 3.6-6. The general plans for the cities of Escondido, Poway, and San Diego do not identify locally important mineral resources. The community plans for Bonsall, Fallbrook, and Rainbow; the regional plans prepared for the North County Sub-region and the San Diego Association of Governments; the Integrated Natural Resources Management Plan for Marine Corps Air Station Miramar; and the San Diego County General Plan also do not identify locally important mineral resources. The City of San Diego and the San Diego County General Plans identify only the MRZs shown on Figure 3.6-6.

### 3.6.2 Regulatory Setting

This subsection summarizes federal, state, and local laws; regulations; and standards that govern geology, soils, and mineral resources.

#### 3.6.2.1 Federal

**1997 Uniform Building Code**

The 1997 Uniform Building Code (UBC) specifies acceptable design criteria for structures with respect to seismic design and load-bearing capacity. Seismic risk zones have been developed based on the known distribution of historic earthquake events and frequency of earthquakes in a given area. These zones are generally classified on a scale from I (least hazard) to IV (most hazard). These values are used to determine the strengths of various components of a building required to resist earthquake damage. Based on the UBC Seismic Zone Maps of the United States, and because of the number of active faults in southern California, the proposed project would be located in the highest seismic risk zone defined by the UBC standard: UBC Zone IV. The State of California has adopted the UBC seismic design and load-bearing capacity criteria in the California Building Code (CBC).

**Clean Water Act**

The Clean Water Act of 1972 (33 United States Code §1251 et seq.) requires states to set standards to protect water quality, including the regulation of stormwater and wastewater discharge during construction and operation of a facility. This includes the creation of the National Pollutant Discharge Elimination System (NPDES), a system that requires states to establish discharge standards specific to water bodies and which regulates stormwater discharge from construction sites through the implementation of a Stormwater Pollution Prevention Plan (SWPPP). Erosion and sedimentation control measures are fundamental components of SWPPPs. In California, the NPDES permit program is implemented and administered by Regional Water Quality Control Boards (RWQCBs). Refer to Section 4.9, Hydrology and Water Quality, for further information.

**Title 49, Part 192 of the Code of Federal Regulations**

Title 49, Part 192 of the Code of Federal Regulations outlines the minimum federal safety standards for the transportation of natural gas and other gas by pipeline, including pipeline facilities and the transportation of gas within the limits of the outer continental shelf. Subparts A through P summarize the
minimum requirements for the selection and qualification of pipe components, corrosion control regulations, pipeline testing, pipeline integrity management, and additional pipeline design specifications. Section 192.917 (b) requires pipeline operators to incorporate topographic data, soil conditions, and earthquake fault data into evaluations regarding outside force threats. Specific data requirements are described in Appendix A of the American Society of Mechanical Engineers document B31.8S: Managing System Integrity of Gas Pipelines.

3.6.2.2 State

**Alquist-Priolo Earthquake Fault Zoning Act**
The purpose of the Alquist-Priolo Earthquake Fault Zoning Act of 1972 is to regulate development near active faults to mitigate the hazard of surface fault rupture. The act requires disclosure to potential real estate buyers of the existence of faults nearby and a 50-foot setback from faults for new, occupied buildings. While the act does not specifically regulate natural gas pipelines, it does define areas where fault rupture is most likely to occur. Under the act, an active fault is defined as one that exhibits evidence that surface rupture has occurred within the last 11,000 years (i.e., Holocene activity). The State of California has identified active faults within California and has delineated “earthquake fault zones” along active faults.

**Seismic Hazards Mapping Act**
The Seismic Hazards Mapping Act of 1990 provides a statewide seismic hazard mapping and technical advisory program to assist cities and counties in fulfilling their responsibilities for protecting the public health and safety from the effects of strong ground shaking, liquefaction, landslides, or other ground failure and seismic hazards caused by earthquakes. Mapping and other information generated pursuant to the Seismic Hazards Mapping Act is to be made available to local governments for planning and development purposes. The state requires that (1) local governments incorporate site-specific geotechnical hazard investigations and associated hazard mitigation as part of the local construction permit approval process; and that (2) the agent for a property seller, or the seller if acting without an agent, must disclose to any prospective buyer if the property is located within a seismic hazard zone. The State Geologist is responsible for compiling seismic hazard zone maps.

**California Government Code**
California Government Code Sections 65302(f) and 65302 require cities to take seismic and other natural hazards into account in their planning programs and to outline them in their general plans.

**California Building Standards Code**
The 2016 CBC is based on the 2006 International Building Code, with the addition of more extensive structural seismic provisions. The CBC was published by the California Building Standards Commission on July 1, 2016, and became effective January 1, 2017. The CBC is contained in Title 24 of the California Code of Regulations, California Building Standards Code, and is a compilation of three types of building standards with three different origins:

- Building standards that have been adopted by state agencies without change from building standards contained in national model codes;
- Building standards that have been adopted and adapted from the national model code standards to meet California conditions; and
- Building standards authorized by the California legislature that constitute extensive additions not covered by the model codes that have been adopted to address particular California concerns.
Seismic sources and the procedures used to calculate seismic forces on structures are defined in Section 1613 of the CBC. The CBC requires that all structures and permanently attached nonstructural components be designed and built to resist the effects of earthquakes. The code also includes grading and other geotechnical issues, building specifications, and non-building structures.

### 3.6.2.3 Regional and Local

**Regional Water Quality Control Board**
The San Diego RWQCB manages water quality for the jurisdictions within the study area. If construction disturbs a surface area greater than 1 acre, coverage under the NPDES Construction General Permit from the RWQCB would be needed. To obtain coverage, a Notice of Intent would be filed with the RWQCB, and a SWPPP would be prepared that would include information about the proposed project; monitoring and reporting procedures; and best management practices, including those for erosion, sedimentation, and stormwater runoff control. The SWPPP would be based on final engineering design and would include all components of a proposed project.

**County of San Diego General Plan**
The following goals and policies from the San Diego County General Plan are relevant to development of a natural gas pipeline; these provide information as to what a development would need to comply with in order to be approved by the community (County of San Diego 2015):

**Goal S-7 Reduced Seismic Hazards.** Minimized personal injury and property damage resulting from seismic hazards.

- **S-7.1 Development Location.** Locate development in areas where the risk to people or resources is minimized. In accordance with the California Department of Conservation Special Publication 42, require development be located a minimum of 50 feet from active or potentially active faults, unless an alternative setback distance is approved based on geologic analysis and feasible engineering design measures adequate to demonstrate that the fault rupture hazard would be avoided.

- **S-7.2 Engineering Measures to Reduce Risk.** Require all development to include engineering measures to reduce risk in accordance with the CBC, UBC, and other seismic and geologic hazard safety standards, including design and construction standards that regulate land use in areas known to have or potentially have significant seismic and/or other geologic hazards.

- **S-7.3 Land Use Location.** Prohibit high occupancy uses, essential public facilities, and uses that permit significant amounts of hazardous materials within Alquist-Priolo and County special study zones.

**Goal S-8 Reduced Landslide, Mudslide, and Rock Fall Hazards.** Minimized personal injury and property damage caused by mudslides, landslides, or rock falls.

- **S-8.1 Landslide Risks.** Direct development away from areas with high landslide, mudslide, or rock fall potential when engineering solutions have been determined by the County to be infeasible.

- **S-8.2 Risk of Slope Instability.** Prohibit development from causing or contributing to slope instability.
Rainbow Community Plan

The Rainbow Community Plan Area (CPA), along with the entire Southern California region, lies within a zone of high earthquake activity. Although no known active faults are present within the CPA, three faults indirectly affect the CPA: the San Jacinto fault, the San Andreas system, and the Coronado Bank fault system. All of these faults have the ability to produce earthquakes above magnitude six, and the Rainbow CPA would be susceptible to earthquake shaking and possible damage.

The following goal and policy from the Rainbow Community Plan are relevant to a natural gas pipeline; the goal and policy provides information as to what a development would need to comply with in order to be approved by the community (County of San Diego 2014):

**Goal S1.1.** The prevention of the loss of life and the destruction of property resulting from earthquakes.

**Policy S1.1.1.** Require new development to comply with County seismic codes.

City of Poway General Plan

The City of Poway General Plan establishes goals and policies to provide guidance in the growth of the city. The following geology and soils resources policies were identified under Goal VIII in the City of Poway General Plan. Goal VIII states that it is the goal of the City of Poway to minimize injuries, loss of life, and property damage resulting from natural and man-made hazards. These policies dictate strategies for the community to follow in reviewing applications for development; the strategies provide information as to what design elements and requirements would be needed for receiving approval for development.

The following policies from the City of Poway General Plan are relevant to a natural gas pipeline: (City of Poway 1991)

**Policy B – Geologic Hazards.** The community should be protected against the hazards associated with geologic formations, particularly landslides, through proper land use policies and mitigation. Strategies include:

- Compare all development applications with the Geographic Information Management Systems (GIMS) mapping system to determine if significant geologic hazards exist.
- Investigations performed by a qualified engineering geologist or soil engineer shall be required for all new development review applications.
- Include, as a condition of approval, the recommendations of the engineering geologist for geologic hazard mitigation and the soils engineer for soils related issues.
- Development within unstable slope and landslide areas will be prohibited unless adequate measures are taken to protect against slippage.
- Establish and maintain proper soil management techniques to reduce the adverse effects of soil-related problems, such as shrink-swell behavior, erosion runoff, and potential septic tank failure.

**Policy C – Seismic Safety.** Seismic hazards should be controlled to a level of acceptable risk through the identification and recognition of potentially hazardous conditions and areas. Strategies include:

- Take all appropriate actions to identify and mitigate seismic hazards such as ground shaking, ground rupture, landslides, liquefaction and structural hazards.
The GIMS mapping system and the seismic matrix shall be used to determine if the probability of a seismic hazard exists.

Where it has been determined that there is the probability of a seismic hazard, an investigation by a qualified engineering geologist shall be required.

City of Escondido General Plan
The City of Escondido’s Community Protection element of the General Plan addresses issues such as flood and fire hazards, geologic and seismic activity, and hazardous materials. Although the Alquist-Priolo Earthquake Fault Zoning Act identifies no active faults within Escondido, several faults are present in the vicinity. The City of Escondido regulates development in steep slope areas, which protects against floods, erosion, landslides, and fire hazards. (City of Escondido 2012)

City of San Diego General Plan
The City of San Diego General Plan’s Public Facilities, Services, and Safety element contains policies related to geologic and seismic hazards. These policies dictate strategies for the community to follow in reviewing applications for development; the strategies provide information as to what design elements and requirements would be needed for receiving approval for development. The following policy is relevant to a natural gas pipeline within the city (City of San Diego 2015):

PF-Q.1. Protect public health and safety through the application of effective seismic, geologic, and structural considerations.

- Ensure that current and future community planning and other specific land use planning studies continue to include consideration of seismic and other geologic hazards. This information should be disclosed, when applicable, in the California Environmental Quality Act (CEQA) document accompanying a discretionary action.
- Maintain updated citywide maps showing faults, geologic hazards, and land use capabilities, and related studies used to determine suitable land uses.
- Require the submission of geologic and seismic reports, as well as soils engineering reports, in relation to applications for land development permits whenever seismic or geologic problems are suspected.
- Coordinate with other jurisdictions to establish and maintain a geologic “data bank” for the San Diego area.
- Regularly review local lifeline utility systems to ascertain their vulnerability to disruption caused by seismic or geologic hazards and implement measures to reduce any vulnerability.
- Adhere to state laws pertaining to seismic and geologic hazards.

3.6.3 Draft Significance Criteria

Had an impact analysis been completed for the proposed project, significance criteria would likely have been based on CEQA Guidelines Appendix G. An impact might have been considered significant if the project would:

a) Expose people or structures to potential substantial adverse effects, including the risk of loss, injury, or death involving:

i. Rupture of a known fault, as delineated on the most recent Alquist-Priolo Earthquake Fault Zoning Map issued by the State Geologist for the area, or based on other substantial
evidence of a known fault. Refer to Division of Mines and Geology Special Publication 42

ii. Strong seismic ground shaking

iii. Seismic-related ground failure, including liquefaction

iv. Landslides

b) Result in substantial soil erosion or the loss of topsoil;

c) Be located on a geologic unit or soil that is unstable, or that would become unstable as a result of the project, and potentially result in on- or off-site landslide, lateral spreading, subsidence, liquefaction or collapse;

d) Be located on expansive soil, as defined in Table 18-1-B of the UBC (1994), creating substantial risks to life or property;

e) Have soils incapable of adequately supporting the use of septic tanks or alternative wastewater disposal systems where sewers are not available for the disposal of waste water;

f) Result in the loss of availability of a known mineral resource that would be of value to the region and state residents; or
